

Big Data (H/M) Lab Task 1

Task Description

In this task you should start with the Spark Tutorial 2 code-base that you can find on the Moodle page. If you have not watched through the provided videos describing map, flatmap and reduce functions used in this exercise, then I recommend that you watch that first.

Your task is to create a new Spark application (with a new main class in the *uk.ac.gla.dcs.bigdata.apps* package) that calculates the number of games in the provided dataset that will work on Windows XP, as specified in part of the 'pcminreqstext' (PC minimum requirements text) data field and also removes any games that have identical titles. It should then print out the titles of the remaining games to standard output on the driver. Games should be processed in parallel using Spark in local mode. You may reuse any code that you wish from Tutorial 2. As part of your implementation, you should implement a new spark function classes as needed. You should avoid using Spark SQL and lambda expressions for this task.

Hints

Removing games with identical titles can be done with a reducer. Encoders do not support serialization of lists directly, and as such you need to create a custom class with a list variable instead to accomplish this.
